## ABSTRACT

Cold-adapted species are expected to reach their largest distribution range during a part of the Ice Ages while the post-glacial warming leads to their range contracting toward high latitude and high altitude areas. This results in extant allopatric distribution of populations and possibly to trait differentiations (selected or not) or even speciation. Assessing an inter-refugium differentiation or speciation remains challenging for such organisms because of sampling difficulties (several disjunct population) and disagreement on species concept. Here, we assessed post-glacial inter-refugium differentiation and potential speciation among populations of the most common arcto-alpine bumblebee species in European mountains, *Bombus monticola* Smith 1849. Based on mtDNA/nuDNA markers and eco-chemical traits, we performed integrative taxonomic analyses to evaluate alternative species delimitation hypothesis and to assess geographic differentiation between interglacial refugia and speciation in arcto-alpine species. Our results show that trait differentiations occurred between most of South European mountains (i.e. Alps, Balkan, Pyrenees and Apennines) and Arctic regions. We suggest that *monticola* complex actually includes three species: *B. konradini* sp. nov. status distributed in Italy (Central Apennine Mountains), *B. monticola* with five subspecies, including *B. monticola mathildis* ssp. nov. distributed in North Apennine Mountains and *B. lapponicus*. Our results support that post Ice-Age periods can lead to speciation in cold-adapted species through distribution range contraction. We underline the importance of integrative taxonomy approach for rigorous species delimitation and for evolutionary study and conservation of taxonomically challenging taxa.

63

## 64 1. INTRODUCTION

65 Past climatic oscillations have led to significant changes in distributions of species.  
66 However, species responses to climate change depend mainly on their eco-climatic  
67 requirements and tolerances (Hewitt, 2004; Stewart *et al.*, 2010). Pleistocene and Quaternary  
68 climatic cycles triggered massive population movements resulting in periods of species range  
69 reductions (i.e. during cold periods when populations are restricted to refuge areas) for  
70 temperate species followed by periods of species range expansions (i.e. during warmer periods  
71 when populations recolonize at least portions of their initial range) (Reinig, 1937; Hewitt,  
72 2004a; Stewart *et al.*, 2010). These population dynamics have fostered intraspecific divergence  
73 processes leading to differentiation and possibly speciation (Avice, 2000; Hewitt, 2004). On the  
74 other hand, alternative demographic histories and subsequent differentiation patterns can be  
75 expected for cold-adapted species. Assessing accurately consequences of past climate change  
76 on differentiation and speciation process is a key element to better understand and predict the  
77 evolution of future biodiversity and to propose evidence-based mitigation strategies (Rasmont  
78 *et al.*, 2015).

79 While population dynamics of temperate species fostered by past climatic events and  
80 their consequences have been the focus of abundant research (Zagwijn, 1992; Taberlet, 1998;  
81 Hewitt, 1999; Stewart *et al.*, 2010), cold-adapted species have received comparatively far less  
82 attention to date (Mardulyn *et al.*, 2009). Contrary to temperate taxa, cold-adapted species are  
83 thought to have reached their largest distribution range during the Ice Ages (Hewitt, 2011). The  
84 post-glacial warming and subsequent interglacial period is thought to have led to range  
85 contraction of such cold-adapted species toward the high latitude/altitude areas (Barnes *et al.*,  
86 2007; Fedorov *et al.*, 2008; Hewitt, 2011). Such a population dynamic scenario can explain  
87 current allopatric patterns of species distributed in Arctic and southern mountains (i.e. arcto-  
88 alpine species) acting as interglacial refugia. These taxa have their current distribution in the  
89 relicts (refugia) of a widespread distribution fragmented by post-glacial warming (Reinig, 1937;

"This is the peer reviewed version of the following article:

Martinet, B. et al 2018 Following the cold: geographical differentiation between interglacial refugia and speciation in the arcto-alpine species complex *Bombus monticola* (Hymenoptera: Apidae). *Systematic Entomology* 2018 ;Volum 43. s. 200-217 which has been published in final form at doi [10.1111/syen.12268](https://doi.org/10.1111/syen.12268). This article may be used for non-commercial purposes in accordance with Wiley Terms and Conditions for Use of Self-Archived Versions."

90 Mardulyn *et al.*, 2009; Dellicour *et al.*, 2014). In Europe, due to interglacial periods, arcto-  
91 alpine species exhibit a strong pattern of allopatry between Southern mountains (Pyrenees,  
92 Alps, Apennines, Balkans and Caucasus) and Northern areas (arctic regions of North  
93 Scandinavia and Russia). Such allopatric patterns have fostered and still foster gene flow  
94 disruptions leading to divergence and possibly speciation of cold-adapted species (Avice, 2000;  
95 Hewitt, 2004b).

96 However, assessing species delimitation remains challenging because it requires to  
97 arbitrarily select variable traits whose accuracy continues to be debated (Mayr, 1942; De  
98 Queiroz, 2007; Lecocq *et al.*, 2015a). Moreover, it is quite difficult to comprehensively sample  
99 specimens for phylogeographic or speciation studies across vast inhospitable areas such as high  
100 altitude mountains and arctic areas (Hewitt, 2011). This could lead to the underestimation of  
101 the variability within each allopatric population and to misunderstand the allopatric  
102 differentiation process.

103 The integrative taxonomy based on the unified species concept (De Queiroz, 2007) aims  
104 to overcome limitations due to unsettled adequacy of selected diagnostic traits and limited  
105 sampling. First, the approach considers multiple independent lines of evidence to evaluate inter-  
106 population differentiation processes and taxonomic statuses (Schlick-Steiner *et al.*, 2010;  
107 Lecocq *et al.*, 2015a,b). This reduces the likelihood of false taxonomic conclusions driven by  
108 single trait. Second, analyzing multiple traits to investigate inter-population differentiation  
109 allows to increase the amount of information available despite a limited sample size (Lecocq *et*  
110 *al.*, 2011).

111 Among potential organisms of interest for studying climatic oscillation consequences  
112 on cold-adapted species, bumblebees (Hymenoptera, Apidae, *Bombus*) represent a relevant  
113 biological system because some of them (i) live in the coldest areas inhabited by insects, (ii)  
114 have undergone diversification processes during the Pleistocene and Quaternary climatic cycles  
115 (Hines, 2008; Duennes *et al.*, 2012; Martinet *et al.*, 2015a; Rasmont *et al.*, 2015; Dellicour *et*  
116 *al.*, 2016). Their interspecific and inter-population differentiations have been studied for a long  
117 time (e.g., Reinig, 1939). However, different diagnostic traits (morphological traits, DNA  
118 sequences, eco-chemical traits) have been used, resulting in conflicting biological conclusions  
119 (e.g., Gjershaug *et al.*, 2013; Williams *et al.*, 2015). Over the past few years, the efficiency of

"This is the peer reviewed version of the following article:

Martinet, B. et al 2018 Following the cold: geographical differentiation between interglacial refugia and speciation in the arcto-alpine species complex *Bombus monticola* (Hymenoptera: Apidae). *Systematic Entomology* 2018 ;Volum 43. s. 200-217 which has been published in final form at doi [10.1111/syen.12268](https://doi.org/10.1111/syen.12268). This article may be used for non-commercial purposes in accordance with Wiley Terms and Conditions for Use of Self-Archived Versions."

120 available diagnostic characters has been critically discussed and a merging of these traits in an  
121 integrative taxonomic framework has been proposed (e.g. Lecocq *et al.*, 2015a). This provides  
122 the opportunity to efficiently delimitate species for a common cold-adapted bumblebee species  
123 with a strong pattern of allopatry. Moreover, integrative taxonomy can help to define the  
124 subspecies status of allopatric populations (Lecocq *et al.*, 2015a). In bumblebees, subspecies  
125 definition is traditionally based on color pattern variation but this diagnostic character requires  
126 an extensive overview of the inter-individual variability (Bertsch & Schweer, 2012a). However,  
127 color pattern has been shown to be unsuitable for taxonomic delimitation (Vogt, 1909; Bertsch  
128 & Schweer, 2012a; Carolan *et al.*, 2012; Williams *et al.*, 2015) as well as for intraspecific  
129 variation study (Lecocq *et al.*, 2015b,c).

130 Here, we investigated the potential inter-refugium differentiation and speciation within  
131 the most common arcto-alpine bumblebee species in European mountains (Rasmont *et al.*,  
132 2015): *Bombus (Pyrobombus) monticola* Smith 1849. We sampled all the allopatric regions  
133 where the species is known (infra-specific taxa). We analyzed inter-population differentiation  
134 through multiple diagnostic traits: (i) a mtDNA marker (cytochrome oxidase I, COI), (ii) a  
135 nuDNA marker (phosphoenolpyruvate carboxykinase, PEPCK), and (iii) eco-chemical traits  
136 (cephalic labial gland secretions, CLGS). Based on these traits, we developed an integrative  
137 taxonomic approach *sensu* Lecocq *et al.* (2015a,c) to assess the taxonomic status of major  
138 clades. We aim to exemplify the consequences of climate change on the evolution of cold-  
139 adapted bumblebees with a common mountainous species.

## 140 2. MATERIAL & METHODS

### 141 2.1. Model Species

142 *Bombus (Pyrobombus) monticola* Smith 1849 is an arcto-alpine species widespread in  
143 the alpine and sub-alpine stages of the most highest mountain ranges of Europe with isolated  
144 populations in Northern Europe and Mediterranean mountains (Cantabrian Mountains,  
145 Pyrenees, Alps, Apennines, and Balkans but not Caucasus) (Svensson, 1979; Kuhlmann *et al.*,  
146 2014; Rasmont *et al.*, 2015). *Bombus monticola* was confirmed as an unique taxonomic unit by  
147 chemical (cephalic labial gland secretion and enzymology) and genetic analysis (Svensson,  
148 1979; Gjershaug *et al.*, 2013) in comparison with its most similar taxon *B. lapponicus*  
149 (Fabricius, 1793). The analysis of Hines (2008), suggested that *Bombus monticola* diverged

"This is the peer reviewed version of the following article:

Martinet, B. et al 2018 Following the cold: geographical differentiation between interglacial refugia and speciation in the arcto-alpine species complex *Bombus monticola* (Hymenoptera: Apidae). *Systematic Entomology* 2018 ;Volum 43. s. 200-217 which has been published in final form at doi [10.1111/syen.12268](https://doi.org/10.1111/syen.12268). This article may be used for non-commercial purposes in accordance with Wiley Terms and Conditions for Use of Self-Archived Versions."

150 from its sister species *B. lapponicus* about 3 Ma (Hines, 2008). The species displays  
151 geographically differentiated color patterns (Reinig, 1965) that have been used to define five  
152 phenotypically diagnosable allopatric subspecies (Tab.1 Fig 2, (Rasmont *et al.*, 2015)): (i) *B.*  
153 *monticola scandinavicus* Friese 1912 (Fennoscandia), (ii) *B. monticola monticola* Smith 1849  
154 (British Islands), (iii) *B. monticola alpestris* (= *hypsophilus*, Tkalcu 1992) Vogt 1909 (Alps, the  
155 Balkans, and the Olympus Mount), (iv) *B. monticola rondoui* Vogt 1909 (Cantabrian Mountains  
156 and Pyrenees), and (v) *B. monticola konradini* Reinig 1965 (Apennine Mountains) (Figs. 1-2).  
157 We define "*monticola* complex" as *Bombus monticola* ssp. + *Bombus lapponicus* and only  
158 "*monticola*" gathering exclusively all subspecies of *Bombus monticola*.

## 159 2.2. Sampling

160 We sampled 70 specimens including all *B. monticola* taxa (Appendix S1) from all  
161 mountain ranges of Europe: *B. monticola scandinavicus* ( $n= 11$ ) from North Scandinavia, *B.*  
162 *monticola monticola* ( $n=10$ ) from the British Islands, *B. monticola rondoui* ( $n= 9$ ) from the  
163 Pyrenees, *B. monticola alpestris* from the Alps ( $n=9$ ), Balkans ( $n=3$ ) and the Olympus  
164 Mountain ( $n=1$ ) and *B. monticola konradini* (*sensu* Reinig, 1965) from the Central Apennines  
165 (Sibilini Mountains) ( $n= 5$ ) and from the North Apennines ( $n=2$ ). The North Apennines  
166 population, whose geographic distribution includes the highest peaks in the Apuan Alps, is  
167 separated by wide gaps not only from the Central Apennines populations but also from alpine  
168 *alpestris* (almost 230 km). We used the phylogenetically closely related species *B.*  
169 (*Pyrobombus*) *lapponicus* ( $n=10$ ) for comparison (see Cameron *et al.*, 2007) and *B. bimaculatus*  
170 (Cresson 1863) ( $n= 10$ ) to root trees in our genetic analyses. All specimens were killed by  
171 freezing at  $-20^{\circ}\text{C}$ . We considered all taxa without *a priori* taxonomic status and referred to them  
172 as *scandinavicus*, *monticola*, *rondoui*, *alpestris*, *konradini*, *lapponicus*, and *bimaculatus*  
173 (Tab.2). We further split *konradini* into *konradini-N* to indicate the Northern Apennines  
174 population and *konradini-C* to indicate the Central Apennines population.

## 175 2.3. Genetic Differentiation Analyses

176 To investigate the potential genetic differentiation between *B. monticola* taxa, we  
177 sequenced two genes that are commonly used in bee phylogenetic and phylogeographic studies  
178 (e.g. Pedersen, 2002; Cameron *et al.*, 2007; Williams *et al.*, 2012, Dellicour *et al.*, 2015): the  
179 mitochondrial gene COI and the nuclear gene PEPCK. We performed DNA extraction protocol,  
180 polymerase chain reaction (COI primers Apl2013/Aph2931, Pedersen 2002; PEPCK primers

"This is the peer reviewed version of the following article:

Martinet, B. et al 2018 Following the cold: geographical differentiation between interglacial refugia  
and speciation in the arcto-alpine species complex *Bombus monticola* (Hymenoptera: Apidae).

*Systematic Entomology* 2018 ;Volum 43. s. 200-217 which has been published in final form at doi

[10.1111/syen.12268](https://doi.org/10.1111/syen.12268). This article may be used for non-commercial purposes in accordance with Wiley  
Terms and Conditions for Use of Self-Archived Versions."

181 FHv4/RHv4, Cameron *et al.*, 2007), sequencing procedures, and DNA sequence alignment  
182 using the method described in Lecocq *et al.* (2013). We uploaded the resulting COI (938 bp)  
183 and PEPCK (925 bp) sequences in GenBank (accession numbers Appendix S1).

184 We investigated the potential genetic differentiation within *B. monticola* through  
185 haplotype network analyses and phylogenetic inference. We carried out the analyses for each  
186 gene individually. We used the median-joining method to produce haplotype networks with  
187 *Network* 4.6.1.0 ([www.fluxus-engineering.com](http://www.fluxus-engineering.com)). We weighted transversions twice as high as  
188 transitions to reconstruct the network (Lecocq *et al.*, 2015).

189 In phylogenetic analyses, we analyzed each gene with maximum parsimony (MP),  
190 maximum likelihood (ML) and Bayesian (MB) methods. We carried out maximum parsimony  
191 analyses (heuristic method) using Seaview 3.2 (Galtier *et al.*, 1996) with 1,000,000 replicas.  
192 Only high quality trees and the majority rule 50% consensus tree were conserved. For ML and  
193 MB, each gene was partitioned as follows: (i) the nuclear gene (PEPCK) into two exons and  
194 two introns and (ii) each nuclear exon and (iii) the mitochondrial gene (COI) by base positions  
195 (first, second and third nucleotide) to define the best substitution model with JModelTest Server  
196 2.0 (Posada, 2008) using the corrected Akaike information criterion. Best-fitting substitution  
197 models : (i) for COI : GTR+I (1st position), TIM2+I (2nd position), TrN+G (3rd position) ; (ii)  
198 for PEPCK intron 1: TPM1 uf +I ; (iii) for PEPCK exon 1: HKY+I (1st position), JC (2nd  
199 position), TrN+I (3rd position) ; (iv) for PEPCK intron 2: TrN+I ; (v) for PEPCK exon 2 : JC  
200 (1st position), JC (2nd position), JC (3rd position). For maximum likelihood analyses (ML),  
201 we performed 10 independent runs in GARLI 2.0 for both genes (Zwickl, 2006); the topology  
202 and -ln L was the same among replicates. Only the run with the highest likelihood was saved.  
203 We assessed statistical significance of nodes with 10,000 nonparametric bootstrap replicates.  
204 We considered a topology well supported (high confidence) whenever the bootstrap value  
205 (branch supports) was greater than 85% (Hillis & Bull, 1993). We carried out Bayesian  
206 inference analyses (MB) with MRBAYES 3.1.2 (Ronquist & Huelsenbeck, 2003). We achieved  
207 10 independent analyses for each gene (100 million generations, four chains with mixed  
208 models, default priors, saving trees every 100 generations). Then we removed the first  
209 10,000,000 generations as burn-in procedure. Then a majority-rule 50% consensus tree was  
210 constructed. Only branch supports (topologies) with high posterior probabilities ( $\geq 0.95$ ) were

"This is the peer reviewed version of the following article:

Martinet, B. et al 2018 Following the cold: geographical differentiation between interglacial refugia and speciation in the arcto-alpine species complex *Bombus monticola* (Hymenoptera: Apidae). *Systematic Entomology* 2018 ;Volum 43. s. 200-217 which has been published in final form at doi [10.1111/syen.12268](https://doi.org/10.1111/syen.12268). This article may be used for non-commercial purposes in accordance with Wiley Terms and Conditions for Use of Self-Archived Versions."

211 considered statistically significant (Wilcox *et al.*, 2002). We (re) rooted all trees with the taxon  
212 *B. bimaculatus*.

213 To check the robustness of the genetic analyses, we applied the bGMYC method to the  
214 monticola complex (COI gene) to recognize species (threshold) following the protocol of  
215 Lecocq *et al.* (2015c). These analyses were performed with "bGMYC" (Reid & Carstens 2012)  
216 R packages. The stationarity and the modal coalescent/Yule ratio have been assessed to  
217 continue the analysis. A range of probabilities  $> 0.95$  was considered as strong evidence that  
218 taxa were conspecific while a range of probabilities  $< 0.05$  suggested that taxa was  
219 heterospecific (Reid & Carstens 2012). For bGMYC, ultrametric trees have been generated with  
220 BEAST 1.7.4 (Drummond *et al.* 2012) with a phylogenetic clock model to generate a posterior  
221 distribution of trees (length of the MCMC chain: 1 billion generations). The first million  
222 sampled trees as burn-in, using the maximum clade credibility method and setting the posterior  
223 probability limit to 0. Following the method of Lecocq *et al.* (2015c), we based the bGMYC  
224 analysis on 1000 trees sampled every 10 000 generations. For each of these 1000 trees, the  
225 MCMC was made of 100 000 generations, discarding the first 90 000 as burn-in and sampling  
226 every 100 generations. Posterior probability distribution have been applied against the first  
227 sample tree to provide a "heat' map".

228

#### 229 2.4. Molecular Clock - Estimating Divergence Time

230 Following the approach of Duennes *et al.* (2012) and Lecocq *et al.* (2013), we analyzed  
231 the COI dataset in BEAST v1.7.2 (Drummond & Rambaut, 2007) to estimate the divergence  
232 time among different clades. Using the GTR + I model selected by jModeltest, we ran Markov  
233 chain Monte Carlo simulations with the coalescent constant population size tree model and the  
234 relaxed clock model. Considering that no fossils of *Pyrobombus* species are available, the  
235 phylogeny is calibrated with a range date from a molecular study. We specified a range of  
236 possible substitution rates which includes the extreme rate for insect mitochondrial genes  
237 recorded in the literature (e.g. Duennes *et al.*, 2012) using a flat prior ranging from  $1 \times 10^{-9}$  to  
238  $1 \times 10^{-7}$  substitutions site<sup>-1</sup> and year<sup>-1</sup>. Simulations were run for 300 million generations,  
239 sampling every 1000 generations. Four independent runs were assessed in Tracer v1.4.1  
240 (Rambaut & Drummond, 2016) to confirm convergence, determine burn-in, and examine the

"This is the peer reviewed version of the following article:

Martinet, B. *et al* 2018 Following the cold: geographical differentiation between interglacial refugia and speciation in the arcto-alpine species complex *Bombus monticola* (Hymenoptera: Apidae). *Systematic Entomology* 2018 ;Volum 43. s. 200-217 which has been published in final form at doi [10.1111/syen.12268](https://doi.org/10.1111/syen.12268). This article may be used for non-commercial purposes in accordance with Wiley Terms and Conditions for Use of Self-Archived Versions."

241 effective sample size of all posterior parameters. Log files from each run were combined in  
242 LogCombiner v1.6.1 (Rambaut & Drummond, 2016) for final parameter estimates.

### 243 2.5. Eco-Chemical Traits Differentiation

244 We focused on the most studied eco-chemical trait involved in the bumblebee pre-  
245 mating recognition (Baer, 2003; Ayasse & Jarau, 2014): the cephalic labial gland secretions  
246 (CLGS). These secretions are complex mixtures of mainly aliphatic compounds synthesized *de*  
247 *novo* by male cephalic labial glands (Coppée *et al.*, 2008; Lecocq *et al.*, 2011; Žáček *et al.*,  
248 2013). We identified the main component as the compound that had the highest relative  
249 concentration (RA) among all compounds of CLGSs at least in one specimen of the taxon. The  
250 CLGS are species-specific blends with some inter-population variations and are, subsequently,  
251 commonly used for species discrimination and assessment of intraspecific variability in  
252 bumblebees (review in Lecocq *et al.*, 2015a). We extracted the CLGS with 400 µl of n-hexane,  
253 according to De Meulemeester *et al.*, (2011) and Brasero *et al.*, (2015). Samples were stored at  
254 - 40° C prior to the analyses.

255 We qualified the CLGS composition of each sample by gas chromatography-mass  
256 spectrometry using a Focus GC (Thermo Scientific) with a non-polar DB-5 ms capillary column  
257 [5% phenyl (methyl) polysiloxane stationary phase; column length 30 m; inner diameter 0.25  
258 mm; film thickness 0.25 µm] coupled to DSQ II quadrupol mass analyser (Thermo Scientific)  
259 with 70 eV electron impact ionization. We identified each compound using the retention times  
260 and mass spectra of each peak, in comparison to those from the National Institute of Standards  
261 and Technology library (NIST, U.S.A) database. We determined double bond positions (C=C)  
262 by dimethyl disulfide (DMDS) derivatization (Vincenti *et al.*, 1987).

263 We quantified the CLGS compounds with a gas chromatograph Shimadzu GC-2010  
264 system (GC-FID) equipped with a non-polar SLB-5 ms capillary column [5% phenyl (methyl)  
265 polysiloxane stationary phase; column length 30 m; inner diameter 0.25 mm; film thickness  
266 0.25 µm] and a flame ionization detector. We quantified the peak areas of compounds in GC  
267 solution post-run (Shimadzu Corporation) with automatic peak detection and noise  
268 measurement. The relative areas (RAs, expressed in %) of compounds in each sample were  
269 calculated by dividing the peak areas of compounds by the total area of all compounds. We  
270 excluded compounds for which RA were less than 0.1% for all specimens (De Meulemeester  
271 *et al.*, 2011). The data matrix for each taxon was based (Table S2) on the alignment of each

"This is the peer reviewed version of the following article:

Martinet, B. et al 2018 Following the cold: geographical differentiation between interglacial refugia and speciation in the arcto-alpine species complex *Bombus monticola* (Hymenoptera: Apidae). *Systematic Entomology* 2018 ;Volum 43. s. 200-217 which has been published in final form at doi [10.1111/syen.12268](https://doi.org/10.1111/syen.12268). This article may be used for non-commercial purposes in accordance with Wiley Terms and Conditions for Use of Self-Archived Versions."

272 relative proportion of compound between all samples performed with GCAaligner 1.0 (Dellicour  
273 & Lecocq, 2013).

274 For GC/MS and GC-FID analyses, we injected 1  $\mu$ L, using a splitless injection mode  
275 (injector temperature of 220° C) and helium as carrier gas (1 mL/min, constant velocity of  
276 50cm/s). The oven temperature (of the column)was programmed isothermal at 70° C for 2 min  
277 and then rising from 70° C to 320° C at a rate of 10°C/min. The temperature was then held  
278 isothermal at 320° C for 5 min.

279 To facilitate the alignment of compounds and their identification, before each sample  
280 injection, a standard (Kovats) was injected containing a mix of hydrocarbons (alkanes) from  
281 C10 (decane) to C40 (tetracontane). Kovats indices were calculated with GCKovats 1.0  
282 according to the method described by Dellicour & Lecocq (2013).

283 We performed statistical comparative analyses of the CLGSs using R environment (R  
284 Development Core Team, 2013) to detect CLGS differentiations between *B. monticola* taxa.  
285 We used a clustering method, computed with the unweighted pair-group method with average  
286 linkage (UPGMA) based on Canberra distance matrices (RA of each compound) (R package  
287 ape; Legendre & Legendre, 2004; Paradis *et al.*, 2004), to detect the divergence between taxa  
288 in the CLGS composition. We assessed the uncertainty in hierarchical cluster analysis using p-  
289 values calculated by multiscale bootstrap resampling with 100,000 bootstrap replications  
290 (significant branch supports >0.85) (R package pvclust, Suzuki & Shimodaira 2011). We  
291 assessed CLGS differentiations between taxa by performing a permutation multivariate analysis  
292 of variance using distance matrix (PerMANOVA) (R package vegan, Oksanen *et al.*, 2011).  
293 When a significant difference was detected, we performed a pairwise multiple comparison with  
294 an adjustment of p-values (Bonferroni correction) to avoid type I errors. We determined specific  
295 compounds of each taxon (indicator compounds) with the indicator-value (IndVal) method  
296 (Dufrêne & Legendre, 1997; Claudet *et al.*, 2006). This value is the product of relative  
297 concentration and relative occurrence frequency of a compound within a group. The statistical  
298 significance of an indicator compound (threshold of 0.01) was evaluated with a randomization  
299 procedure.

## 300 2.6. Morphological Analyses

"This is the peer reviewed version of the following article:

Martinet, B. et al 2018 Following the cold: geographical differentiation between interglacial refugia and speciation in the arcto-alpine species complex *Bombus monticola* (Hymenoptera: Apidae). *Systematic Entomology* 2018 ;Volum 43. s. 200-217 which has been published in final form at doi [10.1111/syen.12268](https://doi.org/10.1111/syen.12268). This article may be used for non-commercial purposes in accordance with Wiley Terms and Conditions for Use of Self-Archived Versions."

301 A total of 60 specimens were subjected to morphological analysis to discriminate *B.*  
302 *lapponicus*, *B. konradini* and *B. monticola*. We included only workers to have a sufficient  
303 sampling and because the differences in metabasitarsus measurements were more pronounced  
304 in females than males. We selected the maximum length and width metabasitarsus distance in  
305 reference to the work of Gjershaug *et al.* (2013) and we calculated the ratio (max length/max  
306 width) of these two measures to reduce the effect of body size on this morphological analysis.  
307 One picture was taken for each measurement and specimen using a binocular coupled with a  
308 digital camera (Nikon D70). The specimen was positioned in a way to maximize the focus of  
309 the metabasitarsus. The maximum metabasitarsus distance was measured on the picture with  
310 the software ImageJ 1.5 (Abràmoff *et al.*, 2004) (Tab. 1, Appendix S3). Kruskal-Wallis analyses  
311 (Kruskal-Wallis test and Multiple comparison test after Kruskal-Wallis, "pgirmess" R-package,  
312 Siegel & Castellan, 1988) were performed using R (R Development Core Team, 2013) to  
313 compare the different studied taxa.

#### 314 2.7. Data Integration and Decision Framework

315 Assuming that species diagnosis and inter-population differentiation are more efficient  
316 in a multiple evidence based approach (De Queiroz, 2007; Schlick-Steiner *et al.*, 2010), we  
317 proposed a species delimitation hypothesis according to our genetic and CLGS criteria based  
318 on the method performed by Lecocq *et al.* (2015a) derived from the approach established by  
319 Schlick-Steiner *et al.* (2010). In this method, all criteria used in the integrative approach must  
320 be convergent to assign the specific status. This strict approach could lead to underestimate the  
321 species differentiation but reduce the taxonomic inflation (Lecocq *et al.*, 2015a) We assigned  
322 the species status to a taxon (with a high degree of certainty) if this taxon: (i) was genetically  
323 differentiated in all genetic markers (unique haplotype); (ii) constituted a monophyletic group  
324 with high branch support; (iii) was significantly differentiated in CLGS compositions  
325 (including IndVal indicator compounds, PerMANOVA, high bootstrap values > 0.85) (Lecocq  
326 *et al.*, 2015a). We assigned the subspecies taxonomic status to phenotypically distinct allopatric  
327 populations with differentiation in some traits but not all in order to highlight these populations  
328 displaying of a such differentiation (originality) and to reduce the "underestimate's risk" of our  
329 strict approach to assign species status by naming them as a subspecies (Hawlitshchek *et al.*,  
330 2012; Ennen *et al.*, 2014; Lecocq *et al.*, 2016).

#### 331 2.8. Identification and Type Revision

"This is the peer reviewed version of the following article:

Martinet, B. et al 2018 Following the cold: geographical differentiation between interglacial refugia and speciation in the arcto-alpine species complex *Bombus monticola* (Hymenoptera: Apidae). *Systematic Entomology* 2018 ;Volum 43. s. 200-217 which has been published in final form at doi [10.1111/syen.12268](https://doi.org/10.1111/syen.12268). This article may be used for non-commercial purposes in accordance with Wiley Terms and Conditions for Use of Self-Archived Versions."

332 The type series of *Bombus lapponicus konradini* Reinig 1965 are presently at the  
333 Zoologische Staatssammlung München and have been revisited for this study. The  
334 identification of other studied taxa was checked with traditional identification keys such as  
335 Løken (1973) and Gjershaug *et al.* (2013).

### 336 3. RESULTS

#### 337 3.1. Inter-Taxa Differentiation

338 Haplotype network analysis revealed six unique haplotypes for COI and two for PEPCK  
339 (Fig.3) within *B. monticola* taxa complex. *konradini*-C was the only taxon displaying unique  
340 COI (6.8 % sequence difference from *monticola alpestris* and 5.3% from *lapponicus*) and  
341 PEPCK (0.7% sequence difference from *monticola* and 0.97% from *lapponicus*) haplotypes in  
342 the ingroup. All phylogenetic analyses (MP, ML and MB) of each single gene showed a similar  
343 topology with clades corresponding to haplotype groups found in the networks. Analyses  
344 showed strong support for all groups, but the position of *konradini*-C was variable in the clade  
345 in our phylogenetic analyses, and hence remains uncertain (Fig.3). Phylogenetic analyses on  
346 PEPCK showed two main lineages within "*monticola*" (Fig.3): the central Apennines lineage  
347 (*konradini*-C, hereafter referred to simply as *konradini*) and the main lineage (all other taxa).  
348 COI-based trees resolved *konradini* as the sister group to the outgroup *B. lapponicus* rather than  
349 to other lineages of *B. monticola*. Among these last ones, COI phylogenetic trees underlined  
350 some geographic subgroups within "*monticola*" (Fig.3): (i) the northern Apennine lineage of  
351 "*monticola*" (described hereafter as *mathildis* **ssp. nov.**), (ii) a western group including taxa  
352 from Pyrenees (*rondoui*) and Scotland (*monticola*); (iii) an eastern-northern group including  
353 specimens from Sweden (*scandinavicus*) and Alps + Balkans + Olympus Mt. (*alpestris*).

354 Compare to the maximum likelihood and Bayesian methods for COI data, the tree  
355 generated for bGMYC analysis displays significant difference mainly in the branching of  
356 *mathildis* **ssp. nov.** These differences are probably due to the different parameters used in the  
357 BEAST 1.7.4 software to calculate the bGMYC model and because this heat map is plotted  
358 against on a sample tree and not on the consensus tree. The bGMYC analysis (Fig. 4) highlights  
359 several entities with low probabilities (<0.05) to be conspecific with the other ones which match  
360 with the same taxa recognize in the COI tree (MP, ML, MB methods, Fig. 3). This threshold  
361 leads us to consider three prospective species within the *monticola* complex and the comparison  
362 group *B. bimaculatus* as in Fig. 3 where the monophyly of these species is highly supported: (i)

"This is the peer reviewed version of the following article:

Martinet, B. et al 2018 Following the cold: geographical differentiation between interglacial refugia and speciation in the arcto-alpine species complex *Bombus monticola* (Hymenoptera: Apidae). *Systematic Entomology* 2018 ;Volum 43. s. 200-217 which has been published in final form at doi [10.1111/syen.12268](https://doi.org/10.1111/syen.12268). This article may be used for non-commercial purposes in accordance with Wiley Terms and Conditions for Use of Self-Archived Versions."

363 one group including all *lapponicus* (bGMYC conspecificity probabilities between individuals  
364 included in the group, IP >0.98–1), (ii) a group with all *konradini* from Central Apennines (IP  
365 >0.99–1), (iii) one group with all *bimaculatus* (IP >0.98–1), (iv) all *monticola* subspecies (IP >  
366 0.13–0.95) including *rondoui* (IP >0.95–1), *alpestris* (IP >0.95–1), *scandinavicus* (IP >0.98–1),  
367 *monticola* (IP >0.99–1) and *mathildis* nov. spp. (IP >0.99–1) which are significantly  
368 conspecific. The "heap map" (Fig. 4) shows more structure within *B. monticola* ssp. where the  
369 group displays more different haplotypes.

370 In chemical analyses, 103 compounds were detected; 82 in the CLGSs of *B. monticola*  
371 taxa (Appendix S2) except for *konradini* for which we detected only 50 compounds. The  
372 differentiation of CLGS composition between *B. monticola* taxa and outgroup species (*B.*  
373 *lapponicus* and *B. bimaculatus*) was conspicuous (IndVal; PerMANOVA F=115.63 and F=  
374 122.52, p-value < 0.05; Fig.3). Except *konradini*, all other *B. monticola* taxa shared the same  
375 compounds with similar relative concentration (RA) (PerMANOVA F= 6.00 - 13.20, p-value  
376 >0.05) (Appendix S2). Differences between *konradini* and other *B. monticola* taxa were  
377 particularly marked in the first half of the spectrum representing the most volatile molecules.  
378 The relative abundance of several compounds was different compared with the relative  
379 abundance in other taxa of *B. monticola*. The IndVal method highlighted several unique and  
380 diagnostic compounds of *konradini* (Tab. 3; i.e. ethyl tetradecenoate, ethyl tetradecanoate,  
381 hexadec-7-en-1-ol ethyl octadecadienoate, dotriacontane, ethyl octadec-9-enoate). In particular,  
382 *konradini* was characterized by ethyl octadec-9-enoate with a relative abundance of 8.28%  
383 while it had very low relative abundance in other subspecies (median 0.57%). The  
384 discrimination between *konradini* and other *B. monticola* taxa was supported by maximal  
385 bootstrap support values (100%) (Fig.3). This differentiation was confirmed by statistical  
386 analysis (PerMANOVA F= 29.36 p-value < 0.05, between *konradini* and other *B. monticola*  
387 taxa).

### 388 3.2. Taxonomic Status

389 Species status was confirmed for the comparison group *B. bimaculatus* and *B.*  
390 *lapponicus*. According to the mtDNA and nuDNA divergence along with the CLGS  
391 composition differentiation (including main compounds) (Tab. 4), the species status was  
392 assigned to *konradini* (detailed information is given in Supporting information, Appendix S3).  
393 *Bombus konradini* was originally described by Reinig (1965) as a subspecies typical of the

"This is the peer reviewed version of the following article:

Martinet, B. et al 2018 Following the cold: geographical differentiation between interglacial refugia and speciation in the arcto-alpine species complex *Bombus monticola* (Hymenoptera: Apidae). *Systematic Entomology* 2018 ;Volum 43. s. 200-217 which has been published in final form at doi [10.1111/syen.12268](https://doi.org/10.1111/syen.12268). This article may be used for non-commercial purposes in accordance with Wiley Terms and Conditions for Use of Self-Archived Versions."

394 northern Apennines, ranging from the provinces of Genova and Parma to L'Aquila. All other  
395 taxa were included in *B. monticola* but their color pattern (Tab.1) and/or differentiation in  
396 CLGS composition (minor quantitative differences) and/or in COI marker implied their  
397 assignation to the subspecies status. It is important to note the distinction of the north Apennines  
398 (province of Genoa and Parma) *monticola* population (*B. monticola mathildis* **ssp. nov.**) from  
399 the central Apennines taxon (*B. konradini* **nov. status**) and the population from the Alps (*B.*  
400 *monticola alpestris*). Indeed, considering the slight differentiation in COI (0.53% of divergence  
401 from *alpestris*) and the strong divergence in coat color from *alpestris* (Tab.1, Fig.3), the north  
402 Apennines population should have a new subspecies status: *B. monticola mathildis* (detailed  
403 information is given in Supporting information, Appendix S3).

### 404 3.3. Divergence Times among Clades

405 Based on the COI data, the divergence between *B. konradini* (Central Apennines) and  
406 *B. lapponicus* was estimated with a median of 0.79 Ma (min 0.25 - max 1.9 Ma) at the end of  
407 the Günz-Mindel inter-glacial period. The divergence time between the outgroup *bimaculatus*  
408 and the clade "*monticola-lapponicus-konradini*" was estimated with a median of 2.40 Ma (min  
409 1.14 - max 3.88 Ma). In contrast, the divergence time between *lapponicus-konradini* and the  
410 clade "*monticola*" was estimated with a median of 2.30 Ma (min 1.23 - max 4.11 MA. These  
411 last two divergence times correspond approximately to the onset of glaciation events and the  
412 formation of the Bering Strait. The other *monticola* subspecies have diverged recently with a  
413 estimated time of 40,000-18,000 (min 7,500 - max 548,000) years ago.

### 414 3.4. Morphological Analysis

415 Measurements of the ratio maximum length and width metabasitarsus show significant  
416 differences (Kruskal-Wallis multiple comparison  $\chi^2= 32.757$ ; all p-values < 0.05) between  
417 *lapponicus* and *monticola alpestris*, *monticola mathildis* ssp. nov. The ratio is also significantly  
418 different between *konradini* and *monticola* ssp. but not between *monticola alpestris* and  
419 *monticola mathildis* (Fig. S2, Appendix S3). However, between *konradini* and *lapponicus*,  
420 although our results present a clear trend which highlight a larger ratio for *konradini*, there is  
421 no significant differentiation. According these results, *konradini* appears as intermediate  
422 between *monticola sensu stricto* (large metabasitarsus ratio) and *lapponicus* (short  
423 metabasitarsus ratio). Diagnostic morphological characters are summarized in Tab. 1.

## 424 4. DISCUSSION

"This is the peer reviewed version of the following article:

Martinet, B. et al 2018 Following the cold: geographical differentiation between interglacial refugia and speciation in the arcto-alpine species complex *Bombus monticola* (Hymenoptera: Apidae). *Systematic Entomology* 2018 ;Volum 43. s. 200-217 which has been published in final form at doi [10.1111/syen.12268](https://doi.org/10.1111/syen.12268). This article may be used for non-commercial purposes in accordance with Wiley Terms and Conditions for Use of Self-Archived Versions."

#### 425 4.1. Inter-Population Differentiation of *B. monticola*

426 The concordance between genetic differentiation, geographic distribution, and CLGS  
427 divergence of populations suggests a strong intraspecific structure between the subspecies of  
428 *monticola* (Fig.3). The western subspecies (*B. monticola rondoui* from Pyrenees and *B.*  
429 *monticola monticola* from British Islands), the north Apennines population (*B. monticola*  
430 *mathildis* ssp. nov.) and the eastern-northern subspecies (*B. monticola scandinavicus* from  
431 Sweden and *B. monticola alpestris* from Alps, Balkans and Olympus Mt) constitute, with the  
432 COI marker, five differentiated groups in three main lineages which diverged recently (about  
433 40,000 -18,000 years ago based on molecular clock) during the Pleistocene/Quaternary (Fig.3).  
434 This could explain the weak divergence of PEPCCK marker between *monticola* subspecies  
435 (recent divergence) because nuclear genes have a lower mutation rate than mitochondrial genes  
436 (Lunt *et al.*, 1996; Trunz *et al.*, 2016). Such time-estimation matches with the start of the last  
437 post-glacial warming. So, it appears that the geographic pattern is most likely a consequence of  
438 allopatric differentiation and genetic drift triggered by a range fragmentation subsequent to the  
439 last post-glacial warming. We speculate that, at the beginning of the current interglacial time,  
440 taxa have found refuge in southern mountainous areas (Alps and southern peninsulas of Europe)  
441 and Northern Europe by contraction of their distribution areas or range shifting (Hewitt, 1999;  
442 Hewitt & Ibrahim, 2001; Petit *et al.*, 2003; Stewart *et al.*, 2010), similarly to the boreo-montane  
443 leaf beetle (*Chrysomelidae*), *Gonioctena pallida* (Mardulyn *et al.*, 2009). The resulting  
444 allopatry has fostered mtDNA differentiation along with minor differentiation of chemical  
445 reproductive traits similarly to what has already been shown for insular populations of  
446 bumblebees (Lecocq *et al.*, 2013, 2015a).

447 Despite their relative geographic isolation, all other *B. monticola* allopatric taxa  
448 previously recognized by Reinig (1965) are considered as conspecific based on our diagnostic  
449 criteria with a low geographic genetic and phenotypic differentiation (decision framework  
450 Tab.4; Fig.3). They shared overall the same CLGS composition (except some low relative  
451 concentration differences) and are characterized by only a slight genetic differentiation. These  
452 low differentiations, particularly in CGLS composition, can simply be explained by the short  
453 time of divergence due to geographical isolation and intraspecific variability (Lecocq *et al.*,  
454 2011, 2016). Within *Bombus monticola alpestris*, the three sampled populations (Alps, Balkans  
455 and Olympus Mountain) are clearly consubspecific.

"This is the peer reviewed version of the following article:

Martinet, B. et al 2018 Following the cold: geographical differentiation between interglacial refugia  
and speciation in the arcto-alpine species complex *Bombus monticola* (Hymenoptera: Apidae).

*Systematic Entomology* 2018 ;Volum 43. s. 200-217 which has been published in final form at doi

[10.1111/syen.12268](https://doi.org/10.1111/syen.12268). This article may be used for non-commercial purposes in accordance with Wiley  
Terms and Conditions for Use of Self-Archived Versions."

456 4.2. Mountain Top Speciation: *Bombus konradini* nov.status.

457 Contrary to the situation within *B. monticola*, *B. konradini* nov. status displays larger  
458 genetic and chemical traits differentiations (Fig. 3). Allopatry has most likely shaped the  
459 reproductive trait (CLGS) differentiation as observed in other species (Lecocq *et al.*, 2013). The  
460 strong genetic differentiation of *B. konradini* could be explained by an earlier divergence from  
461 the common ancestor with other *B. monticola* lineages, most likely temporally close to the *B.*  
462 *monticola* - *B. lapponicus* complex divergence. Indeed, based on genetic differences in the 16S  
463 gene, Hines (2008) suggested that *B. lapponicus* and *B. monticola* diverged from each other  
464 about 3 Ma. In temperate species, the post Ice-Age recolonization of territories by relict  
465 populations (from refugia), could lead to a new shuffling of the genetic pool by re-contacting  
466 of these populations without speciation (Coyne & Orr, 2004; Hewitt, 2004). The modification  
467 of geographical range could trigger genetic and CLGS differentiation. Indeed, it has been shown  
468 that the reproductive traits including cephalic labial glands secretions can differentiate from  
469 both sides of the physical barriers that may exist between the refuge areas (Lecocq *et al.*, 2013a).  
470 The case of the new species status of *B. konradini* lends strength to the hypothesis that for cold-  
471 adapted taxa, climatic oscillations (*i.e.* interglacial periods) have led to species differentiation  
472 in mountain refuges after geographical separation. Further phylogeographic and phylogenetic  
473 studies, based on larger sampling (including additional closely related species) and other  
474 genetic markers, are needed to accurately assess these hypotheses.

475 Our integrative taxonomic decision framework supported and confirmed the species  
476 status of *B. monticola* compared with its morphologically closely related species (*B.*  
477 *lapponicus*) (Løken, 1973; Svensson, 1979; Cameron *et al.*, 2007; Gjershaug *et al.*, 2013). Our  
478 results also supported the species status of *konradini* which is endemic of alpine levels of the  
479 Central Apennines (Manino *et al.*, 2007) (Fig. 3, Tab. 4). Concerning the eco-chemical traits  
480 (CLGS), *konradini* differed from the other *B. monticola* taxa by lightweight compounds  
481 (volatile molecules) which could have a long distance attractive role (Ayasse *et al.*, 2001).  
482 Therefore, the differentiation of these compounds may be a significant pre-mating reproductive  
483 barrier or may simply reflect divergence times and drift. Besides, according to the results of  
484 COI marker, *konradini* could be more closely related to *B. lapponicus* (Fig.3) than *B. monticola*  
485 taxa as suggested in the original description of Reinig (1965). However, the phylogenetic

"This is the peer reviewed version of the following article:

Martinet, B. et al 2018 Following the cold: geographical differentiation between interglacial refugia and speciation in the arcto-alpine species complex *Bombus monticola* (Hymenoptera: Apidae). *Systematic Entomology* 2018 ;Volum 43. s. 200-217 which has been published in final form at doi [10.1111/syen.12268](https://doi.org/10.1111/syen.12268). This article may be used for non-commercial purposes in accordance with Wiley Terms and Conditions for Use of Self-Archived Versions."

486 position of *konradini* is not completely resolved because of the different tree topologies  
487 between COI and PEPCK results.

488 The species status of *B. konradini* suggests that inter-glacial periods can lead to species  
489 differentiation in mountain refugia in cold-adapted taxa. Unlike the populations of the Alps,  
490 Pyrenees and Balkans, where the interconnection and thus the possibility of exchanges and  
491 conspecificity are likely, the population of the central Apennines is much more isolated from  
492 other mountain chains with a possible endemic speciation (Martin- Bravo *et al.*, 2010). Several  
493 studies have shown the presence of endemic taxa in the Central Apennines (e.g. in amphibians  
494 Mattoccia *et al.*, 2011, Canestrelli & Nascetti, 2008, 2012, in reptiles Nagy *et al.*, 2002, Joger  
495 *et al.*, 2007, in turtles Fritz *et al.*, 2006, in plants Conti *et al.*, 2005; Fuente *et al.*, 2011, Frattaroli  
496 *et al.*, 2013; in bumblebees Lecocq *et al.*, 2013). For example, Lecocq *et al.*, (2013a) provided  
497 evidence that the population of *B. lapidarius* (a Palearctic polytypic species) from the Southern  
498 Italian refugia has experienced genetic and CLGS differentiation during Quaternary glaciations  
499 leading to an incipient speciation process. Populations inhabiting the Mediterranean mountains,  
500 (e.g. the Apennines, one of the few mountain ranges in Europe arranged on a north-south axis)  
501 are characterized by a high genetic diversity (hotspot) with endemic taxa (Ruiz-La-Bourdette  
502 *et al.*, 2012). This ascertainment questions the conspecificity of cold-adapted species with an  
503 allopatric distribution with genetic diversity.

504 These results suggest that *B. monticola* (*sensu stricto*) could be absent in Southern Italy unless  
505 this absence could be due to a sampling bias. Such absence results in lack of sympatry between  
506 *B. monticola* and *B. konradini*, which strikingly contrasts with the sympatry between *B.*  
507 *lapponicus* and *B. monticola* in Scandinavia. We cannot exclude the hypothesis that *B.*  
508 *konradini* could be, although distinct, the "replacement" species of *B. monticola* in Apennines.  
509 Although the results do not tend towards this hypothesis (morphological analysis Fig. 3, Fig.  
510 S2), we may also question the status of *monticola mathildis* and the (phenotypically)  
511 intermediate position of this population between *konradini* and *monticola alpestris* (Alps).  
512 Further genetic analyses (e.g. *Microsatellite*, *SNPs*, *RAD-seq*) are necessary to explore this  
513 hypothesis.4.3. Conservation Remarks on *B. monticola* Complex and the Practice of Integrative  
514 Taxonomy

"This is the peer reviewed version of the following article:

Martinet, B. et al 2018 Following the cold: geographical differentiation between interglacial refugia and speciation in the arcto-alpine species complex *Bombus monticola* (Hymenoptera: Apidae). *Systematic Entomology* 2018 ;Volum 43. s. 200-217 which has been published in final form at doi [10.1111/syen.12268](https://doi.org/10.1111/syen.12268). This article may be used for non-commercial purposes in accordance with Wiley Terms and Conditions for Use of Self-Archived Versions."

515           Considering all taxonomic criteria in our integrative approach (Fig. 3, Tab. 4), we  
516 propose to conserve the subspecies status for five *monticola* taxa (Hawllitschek *et al.*, 2012;  
517 Lecocq *et al.*, 2015a,c, 2016): *B. monticola rondoui* from Pyrenees, *B. monticola monticola*  
518 from British Islands, *B. monticola scandinavicus* from Fennoscandia and *B. monticola alpestris*  
519 from Alps, Balkans, Olympus Mountains and *B. monticola mathildis* ssp. nov. from North  
520 Apennines (formerly included by Reinig within *konradini*). Although the usefulness of  
521 subspecies status in the bumblebee has been criticized and debated (Ebach & Williams, 2009)  
522 during recent decades (Williams, 1991; Bertsch & Schweer, 2012a), we propose that these  
523 allopatric subspecies (partially isolated lineages) represent an important component and a useful  
524 pragmatic taxonomical unit for evolutionary biology and biological conservation in the  
525 evolutionary legacy of *B. monticola* (i.e. Waples, 1995, Phillimore & Owens, 2006; Rasmont  
526 *et al.*, 2008; Patten, 2009; Crowhurst *et al.*, 2011; Braby *et al.*, 2012; Sackett *et al.*, 2014). These  
527 differentiations could be local adaptations to particular environments (Avisé, 2000; Frankham  
528 *et al.*, 2010; Braby *et al.*, 2012; Lecocq *et al.*, 2013a). Therefore, subspecies classification seems  
529 suitable to reflect the intraspecific differentiation within *B. monticola* taxa.

530           The *monticola* complex is a stunning example of the difficulty, in taxonomy, to define  
531 species or subspecies status of a population. Here the integrative taxonomy considering all  
532 criteria independently could provide definitive pieces of evidence for decision. We assigned the  
533 subspecies taxonomic status to phenotypically distinct allopatric groups of populations with  
534 differentiation in some but not all criteria used in the integrative decision framework (i.e.  
535 conflict in selected criteria) (Hawllitschek *et al.*, 2012; Ennen *et al.*, 2014; Lecocq *et al.*, 2015a,c,  
536 2016). Taxonomical conclusions based only on the differentiation of one mitochondrial marker  
537 (e.g. COI barcoding) can lead to weak taxonomic hypothesis (Andriollo *et al.*, 2015; Mutanen  
538 *et al.*; 2016; Trunz *et al.*, 2016) as mitochondrial differentiation may result from sex-specific  
539 characteristics, as lower dispersion for females (Kraus *et al.*, 2009; Lepais *et al.*, 2010), or  
540 mtDNA introgression or incomplete lineage sorting (Bensasson *et al.*, 2001; Lecocq *et al.*,  
541 2015a). Taxonomic diagnosis based on multiple evidence (integrative taxonomy) is the best  
542 approach to avoid overestimation of species diversity which would lead to taxonomic inflation.  
543 Subspecies can be considered as a simple allopatric differentiation (Mayr, 1942; Patten, 2010).  
544 This procedure allows to assign a taxonomic status to any doubtful bumblebee taxa and points  
545 out these taxa for further taxonomic studies (Lecocq *et al.*, 2015a). Moreover, despite the

"This is the peer reviewed version of the following article:

Martinet, B. et al 2018 Following the cold: geographical differentiation between interglacial refugia  
and speciation in the arcto-alpine species complex *Bombus monticola* (Hymenoptera: Apidae).

*Systematic Entomology* 2018 ;Volum 43. s. 200-217 which has been published in final form at doi

[10.1111/syen.12268](https://doi.org/10.1111/syen.12268). This article may be used for non-commercial purposes in accordance with Wiley  
Terms and Conditions for Use of Self-Archived Versions."

546 argument advanced by Williams *et al.* (2015), there is no case in bumblebees where the CLGS  
547 (mate recognition system) was not differentiated between two different species even when  
548 closely related bumblebee species have geographical distributions that do not overlap (e.g. *B.*  
549 *terrestris* (L.) and *B. ignitus* Smith, De Meulemeester *et al.*, 2011 or between *B. patagiatus* and  
550 *B. magnus* where Bertsch & Schweer, (2012b) have shown the differentiation of their cephalic  
551 labial gland secretions).

#### 552 4.4. Conservation Implication of the New Taxonomic Status of *B. konradini* nov. status 553

554 The new taxonomical status has implication for the red list assessments of the here  
555 studied European bumblebees according to the IUCN criteria (Nieto *et al.*, 2014). While  
556 Rasmont *et al.* (2015) assess all taxa lumped into *B. monticola*, the new taxonomic status of *B.*  
557 *konradini* implies an evaluation of its conservation status independently from other *B.*  
558 *monticola* taxa. *Bombus konradini* was described as a rare, geographically very restricted taxon  
559 endemic to the central Apennines of Marche, Umbria, Lazio, Abruzzo and mostly occurring  
560 exclusively at elevations over 1800m (Reinig, 1965; Ricciardelli & Piatti, 2003; Manino *et al.*,  
561 2007, Rasmont *et al.*, 2015). The apparent scarcity of *B. konradini* could lead to significant  
562 genetic drifts (Ricciardelli & Piatti, 2003; Frankham *et al.*, 2010) that might significantly  
563 increase the species extinction risk (Rasmont *et al.*, 2015). Indeed, according Frankham *et al.*  
564 (2010), small and isolated populations of a taxon are inherently more vulnerable to local  
565 extinction due to environmental and demographic stochasticity. It is therefore important to  
566 consider this new taxonomic status in our models and in our future backup plans (mitigation  
567 measures).

## 568 5. ACKNOWLEDGEMENTS

569 The authors thank the Abisko and Tarfala scientific stations (Sweden) for their welcome  
570 and their help in material collection. We acknowledge all people that helped us in our journey  
571 to the Abisko and Tarfala stations: P. Lakare and G. N. Rosqvist (University of Stockholm), M.  
572 Augner and L. Wanhatalo (Abisko Station), H. Savela (Oulu University, Interact  
573 administration), J. Strand and T. Wikstrom (Lansstyrelsen i Norrbottens län Naturvårdsenheten,  
574 Luleå). The authors also thank the Parco Nazionale dei Monti Sibillini and the Parco Nazionale  
575 dell'Appennino Tosco-Emiliano for granting permission to collect in their respective territories.  
576 Special thanks go to P. Salvi (Sibillini), W. Reggioni (Appennino Tosco-Emiliano) and A.

## 986 **AUTHOR CONTRIBUTIONS**

987 Conceived and designed the experiments: BM TL NB CU IV PR. Sampling: BM NB PB MC  
988 PR. Analyzed the data: BM. Wrote the paper: BM TL NB PB MC CU IV JOG, DM PR.

## 989 **FUNDING**

990 The research has received funding from the European Community's Seventh Framework Program, STEP  
991 Project (Status and Trends of European Pollinators, [www.step-project.net](http://www.step-project.net), grant agreement no 244090,  
992 FP7/2007-2013) and from the INTERACT project.

## 993 **SUPPORTING INFORMATION**

994 **Appendix S1.** Table of sampling. Sample code refers to the sample labels used in different  
995 analyses. COI and PEPCK are the GenBank accession numbers for each sample (when  
996 consubspecific samples display the same gene sequence, only one of them has been submitted  
997 to Genbank;).

1029 pair-group method with arithmetic mean (UPGMA) based on a Canberra matrix calculated from  
 1030 the cephalic labial gland secretion matrix of *B. bimaculatus*, *B. lapponicus*, *B. konradini* nov.  
 1031 status, *B. m. rondoui*, *B. m. scandinavicus*, *B. m. monticola*, *B. m. alpestris*, *B. m. mathildis* ssp.  
 1032 nov. The values near nodes represent multiscale bootstrap resampling values (only values >80  
 1033 of main groups are shown except nodes between *B. monticola* subspecies). b) Principal  
 1034 component analysis (PCA) of cephalic labial gland secretion differentiation within *monticola*  
 1035 complex and *B. bimaculatus*. PC1, PC2 and PC3 are the first, the second and the third axes.

1036

1037 **Fig 4. Species recognition heat map.** Species recognition heat map based on ultrametric tree  
 1038 of Cytochrome oxidase 1 (COI) sequences with bGMYC pairwise probability of conspecificity  
 1039 plotted on a sample tree from BEAST. The colored matrix corresponds to the pairwise  
 1040 probabilities of conspecificity returned by the bGMYC method (color scale on the right of the  
 1041 figure). Black spots show the coalescent node for each species.

1042

1043

1044 Tab.1. Range, conservation status and main morphological and colour pattern differences (male  
 1045 and female) between *B. konradini* nov. status, *monticola* subspecies including *mathildis* ssp.  
 1046 nov. and the similar species *B. lapponicus* according to Gjershaug *et al.*, (2013), Løken (1973),  
 1047 Pittioni (1939) and original observations.

	<i>scandinavicus</i>	<i>monticola</i>	<i>rondoui</i>	<i>alpestris</i>	<i>mathildis</i> <i>ssp.nov.</i>	<i>konradini nov</i> <i>status</i>	<i>lapponicus</i>
Range	Fennoscandia	British Islands	Pyrenees	Alps, Balkans, Olympus Mounts	North Apennines	Central Apennines	Fennoscandia
Conservation status	No regression was mentioned	In decline (Fitzpatrick <i>et al.</i> , 2006; Evans & Potts 2013)	In decline (Iserbyt & Rasmont 2012)	Few data show a decline in Italy (Manino <i>et al.</i> , 2007)	No regression was mentioned	Rare and localized (Ricciardelli & Piatti 2003)	Stable (Nieto <i>et al.</i> , 2014)
<b>Female</b>							
	<b>Morphology</b>						
Furrow of gena	The surface between the punctures on vertex is shiny, and there is a slight depression with some punctures near the compound eye					Similar to <i>monticola</i>	The surface between the punctures on vertex is rugose and dull and the furrow is distinct, nearly

"This is the peer reviewed version of the following article:

Martinet, B. et al 2018 Following the cold: geographical differentiation between interglacial refugia and speciation in the arcto-alpine species complex *Bombus monticola* (Hymenoptera: Apidae). *Systematic Entomology* 2018 ;Volum 43. s. 200-217 which has been published in final form at doi [10.1111/syen.12268](https://doi.org/10.1111/syen.12268). 1057 Tab.4. Taxonomic decision table with all criteria used for species delimitation. CLGS, cephalic  
1058 labial gland secretions; COI, cytochrome oxidase 1; PEPCK, phosphoenolpyruvate  
1059 carboxykinase. Morphology indicates if a taxon has a diagnostic morphological character (+/-  
1060 means that morphology is/is not diagnostic). Private haplotypes indicate if a taxon has a specific  
1061 haplotype (+/- means that the taxon has/has not only private haplotype (s). When the taxon  
1062 shares haplotype with other ones, the letters group together taxa that share haplotypes). CLGS  
1063 indicates if the taxon has/has not diagnostic composition of CLGSs with different main  
1064 compounds (+/- means that the taxon has/ has not a specific CLGS composition. When the  
1065 taxon shares CLGS composition with other ones, the letters group together taxa that share  
1066 similar CLGS. COI and PEPCK columns indicate if a taxon forms a strongly supported  
1067 monophyletic group (+/- means that the taxon is/is not a monophyletic group) with MP, ML  
1068 and MB methods . When the taxon is not a distinct monophyletic group, the letters group  
1069 together taxa included in the same monophyletic group). LS= low supported differentiation.

Former taxonomic status	Morphology (Gjershaug <i>et al.</i> , 2013)	Private haplotypes (COI/PEPCK)	CLGS	COI gene / bGMYC	PEPCK gene	Proposed taxonomic status
